CRI-CORE Integration Note v0.1

The Problem

AI systems can propose actions, but most systems do not explicitly control whether those actions are allowed to execute.

Validation, monitoring, and audit exist — but they occur before or after execution.

The moment an action becomes real is often not governed.

Where CRI-CORE Runs

CRI-CORE sits directly before execution.

It evaluates a proposed action and determines:

- allow execution
- block execution

It does not evaluate whether a decision is “good.”

It determines whether the system is allowed to make that decision real.

System Flow

AI / LLM

↓

Tool / API Call

↓

Proposal (normalized)

↓

CRI-CORE (execution gate)

↓

System Mutation (or blocked)

CRI-CORE acts as a deterministic gate at the point where a system attempts to mutate real state.

Minimal Usage

```
commit_allowed = cricore.evaluate(proposal, contract)
```

```
if commit_allowed:
    execute_action()
```

Inputs:

- proposal → structured representation of intended action
- contract → defined authority, roles, and constraints

Output:

- commit_allowed → boolean decision
-

What This Does

- Enforces execution control at the mutation boundary
 - Validates authority, role separation, and constraints
 - Prevents unauthorized actions from executing
-

What This Does Not Do

- Does not evaluate model quality
- Does not replace orchestration or monitoring
- Does not define policy or constraints

It enforces whether defined conditions are satisfied at execution.

Summary

CRI-CORE introduces a deterministic control point at the moment a system attempts to act.

If required conditions are not satisfied:

The action does not execute.
